COLLIDER PHYSICS AND COSMOLOGY

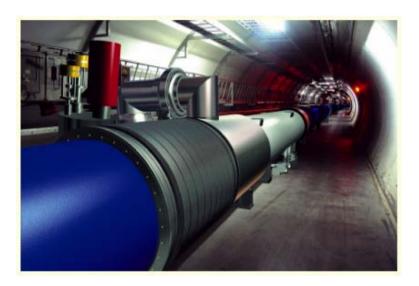

Jonathan Feng
University of California, Irvine

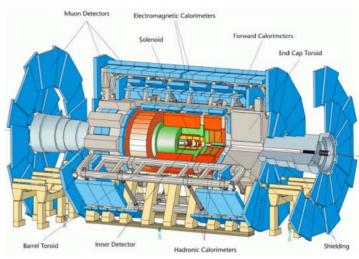

GRG18 and Amaldi7 Sydney, 12 July 2007

LHC

ATLAS

12 July 07

LHC SCHEDULE

Timeline

Conception: ~1984

Approval: 1994

Start of Construction: 2000

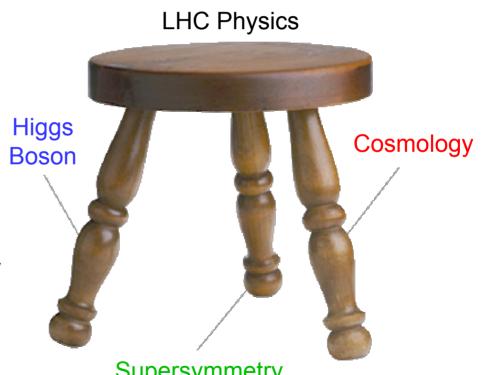

First Collisions: July 2008

Properties

- Proton-proton collider
- $E_{COM} = 14 \text{ TeV}$
- ~10⁷ to 10⁹ top quarks / year
- Probes m ~ 100 GeV 1 TeV

[Tevatron

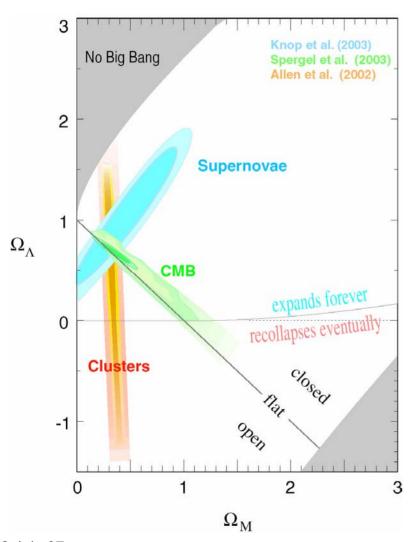

- $E_{COM} = 2 \text{ TeV}$
- ~10² to 10⁴ top quarks / year]

Supersymmetry, Extra Dimensions

12 July 07

COSMOLOGY NOW

Remarkable agreement

Dark Matter: 23% ± 4%

Dark Energy: 73% ± 4%

Baryons: 4% ± 0.4%

Neutrinos: 2% ($\Sigma m_v/eV$)

Remarkable precision

Remarkable results

OPEN QUESTIONS

DARK MATTER

- What is its mass?
- What are its spin and other quantum numbers?
- Is it absolutely stable?
- What is the symmetry origin of the dark matter particle?
- Is dark matter composed of one particle species or many?
- How and when was it produced?
- Why does $\Omega_{\rm DM}$ have the observed value?
- What was its role in structure formation?
- How is dark matter distributed now?

DARK ENERGY

- What is it?
- Why not $\Omega_{\Lambda} \sim 10^{120}$?
- Why not Ω_{Λ} = 0?
- Does it evolve?

BARYONS

- Why not $\Omega_{\rm B}$ ≈ 0?
- Related to neutrinos, leptonic CP violation?
- Where are all the baryons?

THE DARK UNIVERSE

The problems appear to be completely different

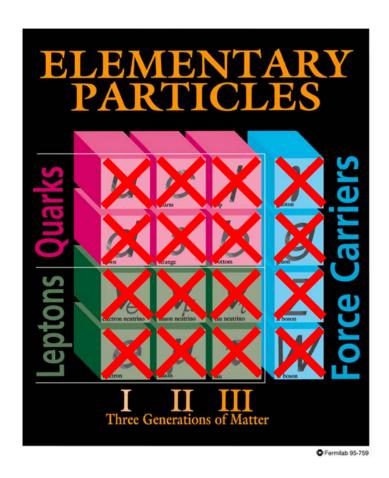

DARK MATTER

- No known particles contribute
- Probably tied to
 M_{weak} ~ 100 GeV
- Several compelling solutions

DARK ENERGY

- All known particles contribute
- Probably tied to $M_{\rm Planck} \sim 10^{19} \, {\rm GeV}$
- No compelling solutions

DARK MATTER

Known DM properties

- Gravitationally interacting
- Not short-lived
- Not hot
- Not baryonic

Unambiguous evidence for new physics

DARK MATTER CANDIDATES

- The observational constraints are no match for the creativity of theorists
- Candidates: primodial black holes, axions, warm gravitinos, neutralinos, sterile neutrinos, Kaluza-Klein particles, Q balls, wimpzillas, superWIMPs, self-interacting particles, self-annihilating particles, fuzzy dark matter,...
- Masses and interaction strengths span many, many orders of magnitude, but not all candidates are equally motivated

NEW PARTICLES AND NATURALNESS

 $m_h \sim 100 \text{ GeV}$, $\Lambda \sim 10^{19} \text{ GeV} \rightarrow \text{cancellation of 1 part in } 10^{34}$

At ~ 100 GeV we expect new particles: supersymmetry, extra dimensions, something!

THE WIMP "MIRACLE"

(1) Assume a new (heavy) particle χ is initially in thermal equilibrium:

$$\chi\chi \leftrightarrow \overline{f}f$$

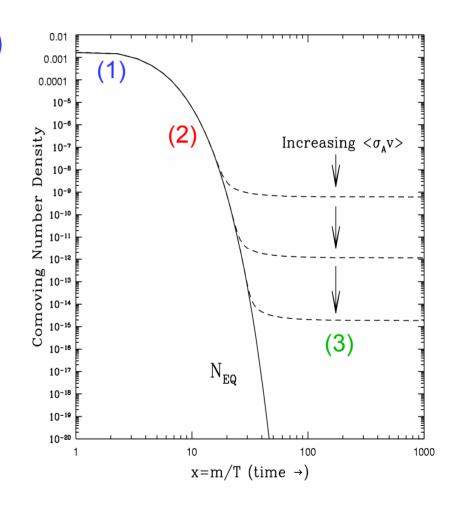

(2) Universe cools:

$$\chi\chi \rightleftharpoons \overline{f}f$$

(3) χ s "freeze out":

$$\chi\chi \not \equiv ff$$

Zeldovich et al. (1960s)

 The amount of dark matter left over is inversely proportional to the annihilation cross section:

$$\Omega_{\rm DM} \sim <_{\sigma_{\rm A}} v >^{-1}$$

- What is the constant of proportionality?
- Impose a natural relation:

$$\sigma_A = k\alpha^2/m^2$$
 , so $\Omega_{DM} \sim m^2$

HEPAP LHC/ILC Subpanel (2006)

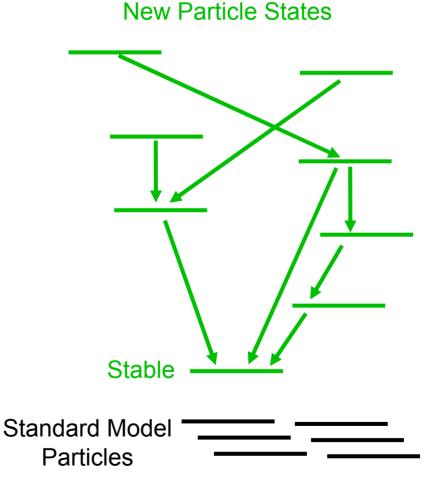

[band width from k = 0.5 – 2, S and P wave]

Remarkable "coincidence": $\Omega_{\rm DM} \sim 0.1$ for m ~ 100 GeV - 1 TeV

STABILITY

 This all assumes that the new particle is stable.

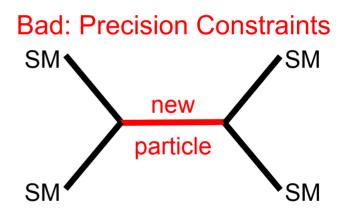

Why should it be?

PRECISION CONSTRAINTS

 Problem: Large Electron Positron Collider, 1989-2000, provided precision constraints on new particles

- Solution: discrete parity → new particles interact in pairs. Lightest new particle is then stable. Cheng, Low (2003); Wudka (2003)
- Dark Matter is easier to explain than no dark matter.

PROLIFERATION OF WIMPS

The WIMP paradigm is thriving. Examples:

- Supersymmetry
 - R-parity → Neutralino DM

Goldberg (1983); Ellis et al. (1984)

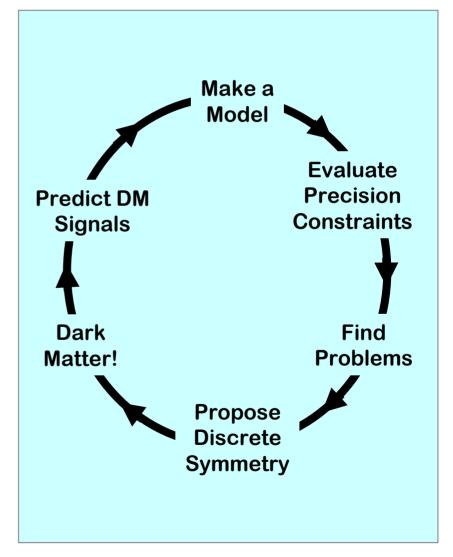

- Universal Extra Dimensions
 - KK-parity → Kaluza-Klein DM

Servant, Tait (2002); Cheng, Feng, Matchev (2002)

- Branes
 - Brane-parity → Branon DM

Cembranos, Dobado, Maroto (2003)

- Little Higgs
 - T-parity → T-odd DM

Cheng, Low (2003)

WIMPS FROM SUPERSYMMETRY

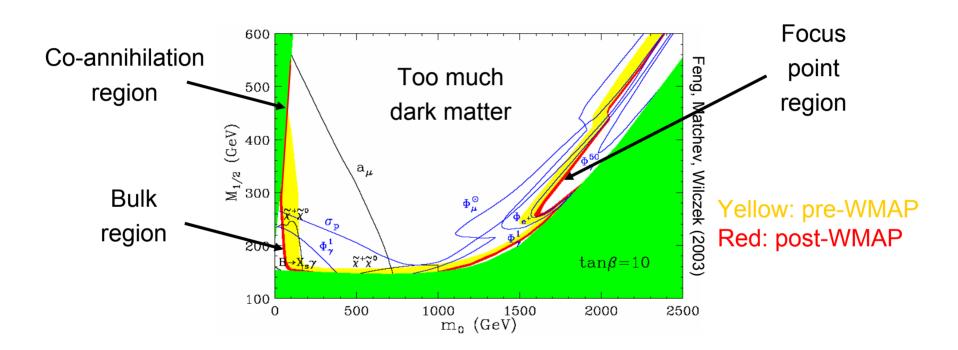

Goldberg (1983); Ellis et al. (1983)

Supersymmetry: many motivations. For every known particle X, predicts a partner particle X

Neutralino $\chi \in (\tilde{\gamma}, \tilde{Z}, \tilde{H}_u, \tilde{H}_d)$

In many models, χ is the lightest supersymmetric particle, stable, neutral, weakly-interacting, mass ~ 100 GeV. All the right properties for WIMP dark matter.

MINIMAL SUPERGRAVITY

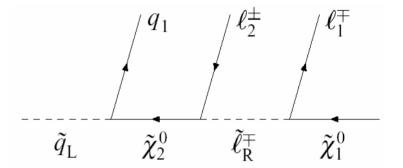

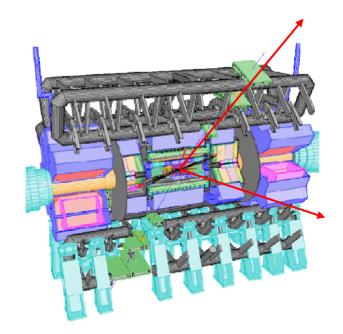

LHC will discover SUSY in this entire region with 1 year's data

WHAT THEN?

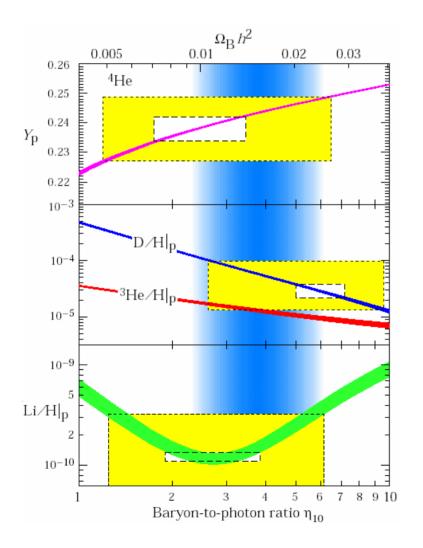

- What LHC actually sees:
 - E.g., qq pair production
 - Each q

 → neutralino χ
 - -2χ 's escape detector
 - missing momentum
- This is not the discovery of dark matter
 - Lifetime > 10^{-7} s → 10^{17} s?

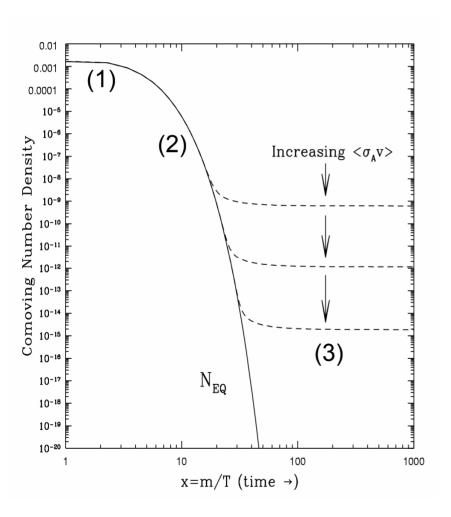

THE EXAMPLE OF BBN

- Nuclear physics → light element abundance predictions
- Compare to light element abundance observations

 $T \sim 1 \text{ MeV}$ t ~ 1 sec

DARK MATTER ANALOGUE

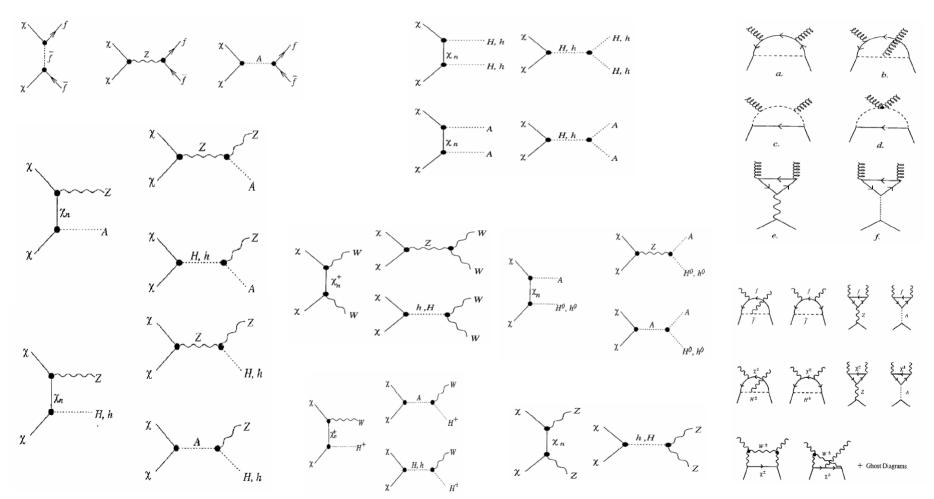

Particle physics →
 dark matter abundance
 prediction

 Compare to dark matter abundance observation

How well can we do?

Contributions to Neutralino WIMP Annihilation

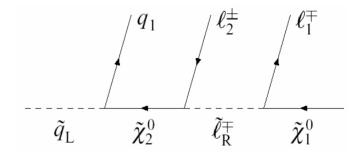

Jungman, Kamionkowski, Griest (1995)

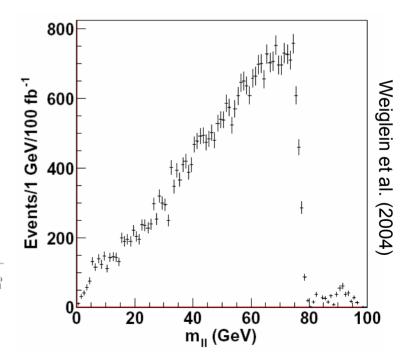

12 July 07

PRECISION SUSY @ LHC

 Masses can be measured by reconstructing the decay chains

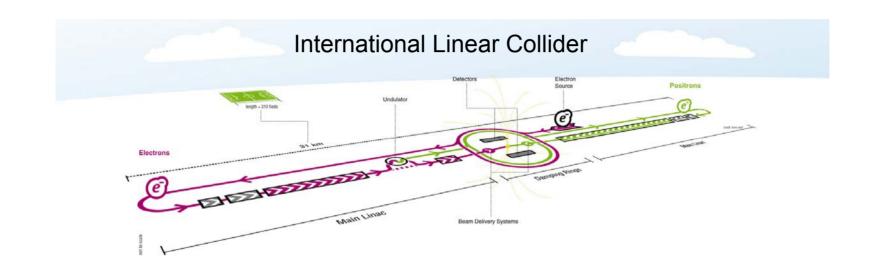

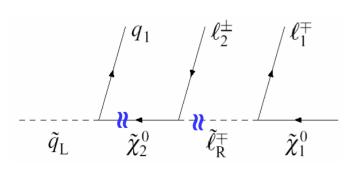

$$\begin{split} \left(m_{ll}^{2}\right)^{\text{edge}} &= \frac{\left(m_{\tilde{\chi}_{2}^{0}}^{2} - m_{\tilde{l}_{R}}^{2}\right)\left(m_{\tilde{l}_{R}}^{2} - m_{\tilde{\chi}_{1}^{0}}^{2}\right)}{m_{\tilde{l}_{R}}^{2}} \\ \left(m_{qll}^{2}\right)^{\text{edge}} &= \frac{\left(m_{\tilde{q}_{L}}^{2} - m_{\tilde{\chi}_{2}^{0}}^{2}\right)\left(m_{\tilde{\chi}_{2}^{0}}^{2} - m_{\tilde{\chi}_{1}^{0}}^{2}\right)}{m_{\tilde{\chi}_{2}^{0}}^{2}} \\ \left(m_{ql}^{2}\right)_{\min}^{\text{edge}} &= \frac{\left(m_{\tilde{q}_{L}}^{2} - m_{\tilde{\chi}_{2}^{0}}^{2}\right)\left(m_{\tilde{\chi}_{2}^{0}}^{2} - m_{\tilde{l}_{R}}^{2}\right)}{m_{\tilde{\chi}_{2}^{0}}^{2}} \\ \left(m_{ql}^{2}\right)_{\max}^{\text{edge}} &= \frac{\left(m_{\tilde{q}_{L}}^{2} - m_{\tilde{\chi}_{2}^{0}}^{2}\right)\left(m_{\tilde{l}_{R}}^{2} - m_{\tilde{\chi}_{1}^{0}}^{2}\right)}{m_{\tilde{l}_{R}}^{2}} \\ \left(m_{qll}^{2}\right)^{\text{thres}} &= \left[\left(m_{\tilde{q}_{L}}^{2} + m_{\tilde{\chi}_{2}^{0}}^{2}\right)\left(m_{\tilde{\chi}_{2}^{0}}^{2} - m_{\tilde{l}_{R}}^{2}\right)\left(m_{\tilde{l}_{R}}^{2} - m_{\tilde{\chi}_{1}^{0}}^{2}\right) \\ &- \left(m_{\tilde{q}_{L}}^{2} - m_{\tilde{\chi}_{2}^{0}}^{2}\right)\sqrt{\left(m_{\tilde{\chi}_{2}^{0}}^{2} + m_{\tilde{l}_{R}}^{2}\right)^{2}\left(m_{\tilde{l}_{R}}^{2} + m_{\tilde{\chi}_{1}^{0}}^{2}\right)^{2} - 16m_{\tilde{\chi}_{2}^{0}}^{2}m_{\tilde{l}_{R}}^{4}m_{\tilde{\chi}_{1}^{0}}^{2}} \\ &+ 2m_{\tilde{l}_{R}}^{2}\left(m_{\tilde{q}_{L}}^{2} - m_{\tilde{\chi}_{2}^{0}}^{2}\right)\left(m_{\tilde{\chi}_{2}^{0}}^{2} - m_{\tilde{l}_{1}^{0}}^{2}\right)\right] / \left(4m_{\tilde{l}_{R}}^{2}m_{\tilde{\chi}_{2}^{0}}^{2}\right) \end{split}$$

12 July 07

PRECISION SUSY @ ILC

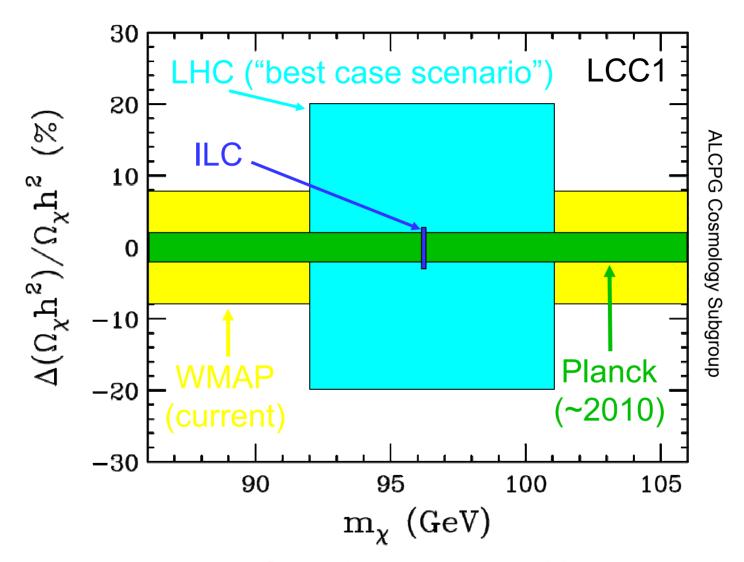

- Collides e⁺e⁻
- Variable beam energies
- Polarizable e- beam

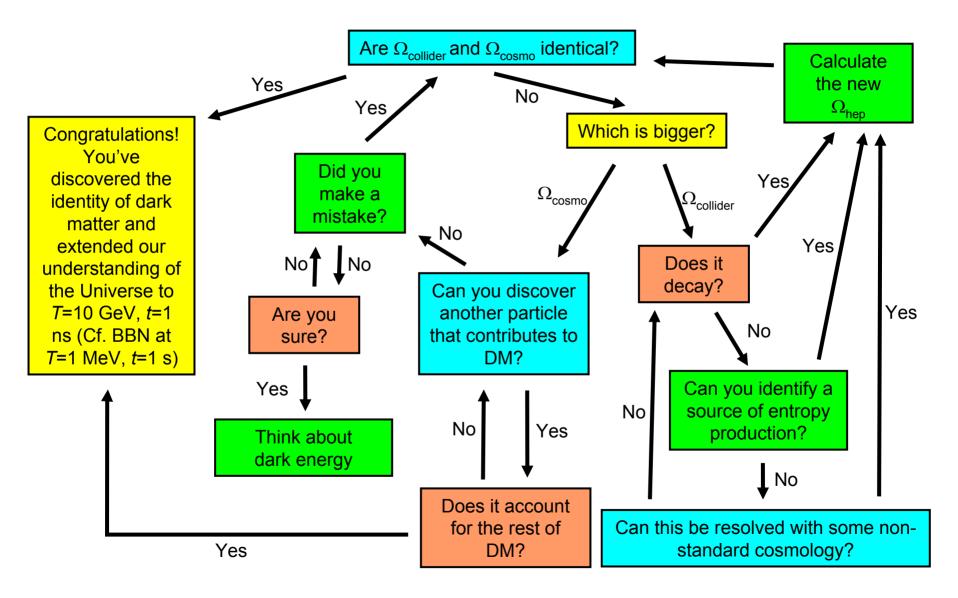

Starts 20??

RELIC DENSITY DETERMINATIONS

% level comparison of predicted $\Omega_{\mathrm{collider}}$ with observed Ω_{cosmo}

IDENTIFYING DARK MATTER

DARK ENERGY

 Freezeout provides a window on the very early universe:

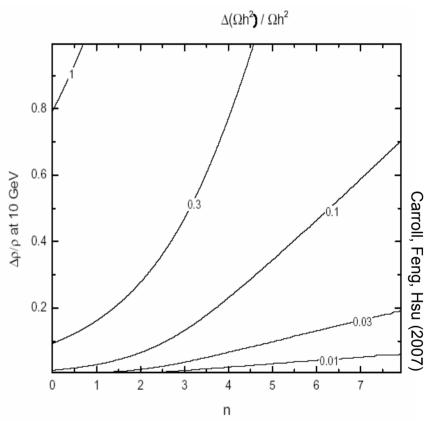

$$\frac{dn}{dt} = -3Hn - \langle \sigma v \rangle \left[n^2 - n_{\rm eq}^2 \right]$$

Dilution from expansion

Probe Friedmann at T ~ 10 GeV:

$$H^2 = \frac{8\pi G_N}{3}(\rho + \Delta \rho) , \quad \Delta \rho \propto T^n$$

n=0 to 8: cosmological constant, tracking dark energy, quintessence, varying G_N , ...

Drees, Iminniyaz, Kakizaki (2007) Chung, Everett, Kong, Matchev (2007)

DIRECT DETECTION

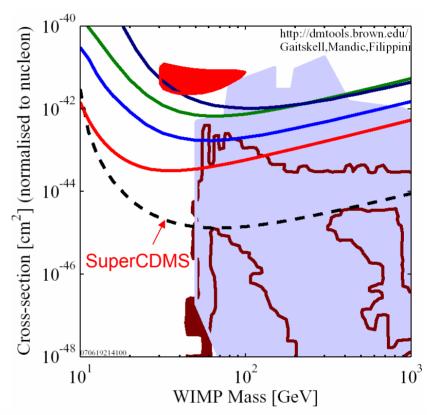

WIMP properties:

 $v \sim 10^{-3} c$

Kinetic energy ~ 100 keV

Local density ~ 1 / liter

 Detected by recoils off ultra-sensitive underground detectors

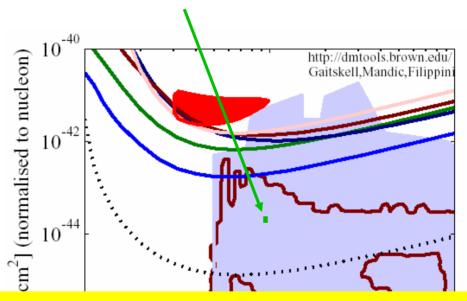

DATA listed top to bottom on plot DAMA 2000 58k kg-days NaI Ann.Mod. 3sigma,w/o DAMA 1996 limit WARP 2.3L, 96.5 kg-days 55 keV threshold ZEPLIN II (Jan 2007) result CDMS (Soudan) 2004 + 2005 Ge (7 keV threshold) XENON10 2007 (Net 136 kg-d, BG Subtract)

XENON10 2007 (Net 136 kg-d, BG Subtract) SuperCDMS (Projected) 25kg (7-ST@Snolab) Baltz and Gondolo 2003

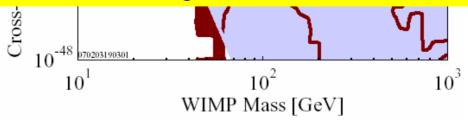

Baltz and Gondolo, 2004, Markov Chain Monte Carlos

DIRECT DETECTION IMPLICATIONS

LHC + ILC $\rightarrow \Delta m < 1$ GeV, $\Delta \sigma / \sigma < 20\%$

Comparison tells us about local dark matter density and velocity profiles, ushers in the age of *neutralino* astronomy

INDIRECT DETECTION IMPLICATIONS

LECC

COLLIDERS ELIMINATE PARTICLE PHYSICS UNCERTAINTIES, ALLOW ONE TO PROBE ASTROPHYSICAL DISTRIBUTIONS

$$\frac{d\Phi_{\gamma}}{d\Omega dE} = \sum_{i} \underbrace{\frac{dN_{\gamma}^{i}}{dE} \sigma_{i} v \frac{1}{4\pi m_{\chi}^{2}}}_{\text{Particle}} \underbrace{\int_{\psi} \rho^{2} dl}_{\text{Physics}}$$
Particle Astro-Physics Physics

Very sensitive to halo profiles near the galactic center

TAKING STOCK

- WIMPs are astrophysically identical
 - Weakly-interacting
 - Cold
 - Stable
- Is this true of all DM candidates?
- No. But is this true of all DM candidates independently motivated by particle physics and the "WIMP miracle"?

 No! SuperWIMPs: identical motivations, but qualitatively different implications

SUPERWIMPS: BASIC IDEA

Feng, Rajaraman, Takayama (2003)

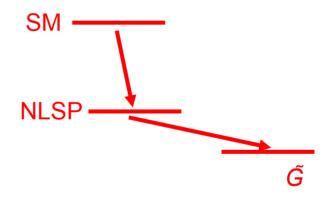

Supersymmetry: Graviton \rightarrow Gravitino \tilde{G} Mass \sim 100 GeV; Interactions: only gravitational (superweak)

• G not LSP

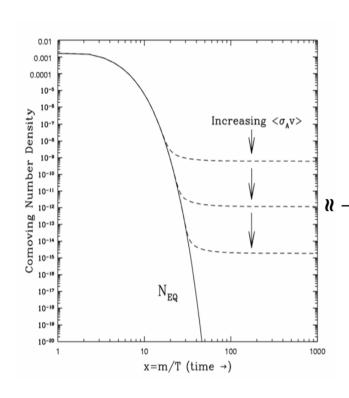

Assumption of most of literature

• \tilde{G} LSP

 Completely different cosmology and particle physics

SUPERWIMP RELICS

- Suppose gravitinos G
 are the LSP
- WIMPs freeze out as usual

But then all WIMPs decay to gravitinos after

 $M_{\rm Pl}^2/M_{\rm W}^3 \sim {\rm seconds\ to\ months}$

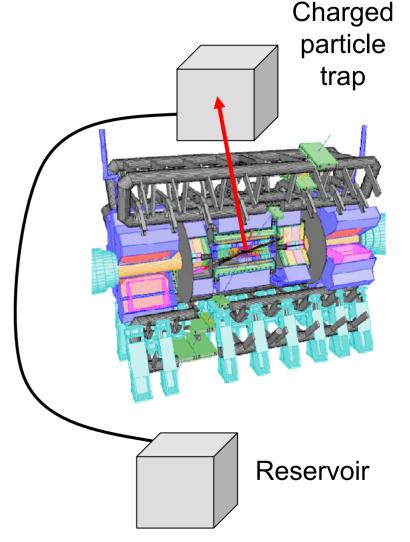

Gravitinos naturally inherit the right density, but interact only gravitationally – they are superWIMPs (also KK gravitons, quintessinos, axinos, etc.)

Feng, Rajaraman, Takayama (2003); Bi, Li, Zhang (2003); Ellis, Olive, Santoso, Spanos (2003); Wang, Yang (2004); Feng, Su, Takayama (2004); Buchmuller, Hamaguchi, Ratz, Yanagida (2004); Roszkowski, Ruiz de Austri, Choi (2004); Brandeburg, Covi, Hamaguchi, Roszkowski, Steffen (2005); ...

Charged Particle Trapping

- SuperWIMPs are produced by decays of metastable particles. These can be charged.
- Charged metastable particles will be obvious at colliders, can be trapped and moved to a quiet environment to study their decays.
- Can catch 1000 per year in a 1m thick water tank

Feng, Smith (2004) Hamaguchi, Kuno, Nakawa, Nojiri (2004) De Roeck et al. (2005)

12 July 07

IMPLICATIONS FROM CHARGED PARTICLE DECAYS

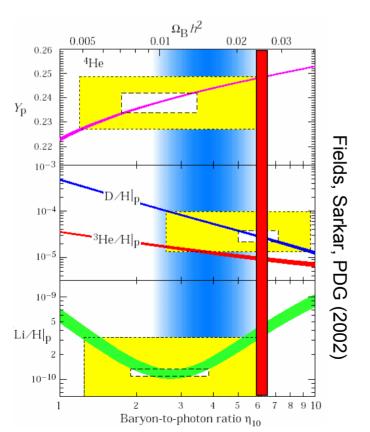

$$\tau(\tilde{l} \to l\tilde{G}) = \frac{6}{G_N} \frac{m_{\tilde{G}}^2}{m_{\tilde{l}}^5} \left[1 - \frac{m_{\tilde{G}}^2}{m_{\tilde{l}}^2} \right]^{-4}$$

- Measurement of τ , $m_{\tilde{l}}$ and $E_{l} \rightarrow m_{\tilde{G}}$ and G_{N}
 - Probes gravity in a particle physics experiment!
 - Measurement of G_N on fundamental particle scale
 - Precise test of supergravity: gravitino is graviton partner
 - Determines $\Omega_{\tilde{G}}$: SuperWIMP contribution to dark matter
 - Determines F: supersymmetry breaking scale, contribution of SUSY breaking to dark energy, cosmological constant

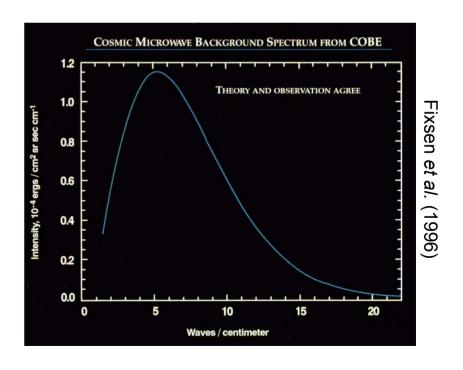

Hamaguchi et al. (2004); Takayama et al. (2004)

SUPERWIMP COSMOLOGY

Late decays can modify BBN (Resolve ⁷Li problem?)

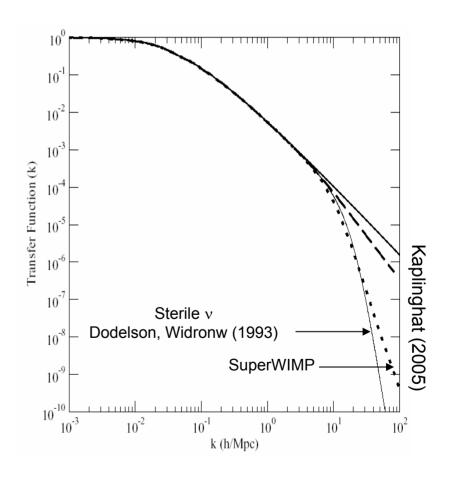

Late decays can modify CMB black body spectrum (µ distortions)

SMALL SCALE STRUCTURE

- SuperWIMPs are produced in late decays with large velocity (0.1c – c)
- Suppresses small scale structure, as determined by λ_{FS} , Q
- Warm DM with cold DM pedigree

Dalcanton, Hogan (2000)
Lin, Huang, Zhang, Brandenberger (2001)
Sigurdson, Kamionkowski (2003)
Profumo, Sigurdson, Ullio, Kamionkowski (2004)
Kaplinghat (2005)
Cembranos, Feng, Rajaraman, Takayama (2005)
Strigari, Kaplinghat, Bullock (2006)
Bringmann, Borzumati, Ullio (2006)

CONCLUSIONS

- Particle Dark Matter
 - As well-motivated as ever
 - WIMPs: Proliferation of candidates
 - SuperWIMPs: Qualitatively new possibilities (warm, metastable, only gravitationally interacting)
- If dark matter is WIMPs or superWIMPs, colliders
 - will produce it
 - may identify it as dark matter
 - may open up a window on the universe at $t \sim 1$ ns

 LHC begins in July 2008 – this field will be transformed by GRG19
